

GUI and CLI, They seem similar except in how they work individually. CLI for example lets you manipulate your system with text commands, including opening up files, creating “closets” and shelves for those files and being able to store them away all simply by using text commands.

And that is just explaining it simply.

GUI on the other hand, is manipulating your system via a series of commands through your mouse and keyboard. Most things are labeled under a file/folder and directory system which makes it much more user friendly even for people who do not be 100% in the tech world.

Whereas with CLI you have to be much more knowledgeable in computer interface language, since you have to manually open or manipulate various parts of a system. This can go as far as to even be used to change your internal system and how it runs and is much faster to deal with.
